Interactive Toy: Red Ball

Pixel Paper - 400 x 400

Graph Paper for Screen Coordinates

Classes

- **Ball.cs** — creates ball, stores ball variables for other modules to access
- **BallCalculator.cs** — Calculators for collisions and other
- **BallController.cs** — handles player inputs
- **Background.cs** — handles background and trail effect

If one assumes that momentum is lost in both directions, since kinetic energy is nondirectional, perhaps it is best to assume that it loses energy in each "direction" proportionally to the sine and cosine of the angle of the bounce. Using this assumption, each bounce causes it to shed 2/3 J from horizontal velocity and 1/3 from vertical potential energy. Under this assumption, there are 1491 bounces, each linearly s[illegible]ller than the last, coming out finally to roughly 250km in distance.
